Sheet 1.—General sea floor ruggedness and topography.

Sheet 2.—General sea floor ruggedness and sun-illuminated topography.

Sheet 3.—Sea floor ruggedness in the >30- to 100-centimeter range and sun-illuminated topography.

Sheet 4.—Sea floor ruggedness in the >1- to 2-meter range and sun-illuminated topography.

Sheet 5.—Sea floor ruggedness in the >2- to 6-meter range and sun-illuminated topography.

DISCUSSION

Introduction

Sea floor mapping in the Stellwagen Bank National Marine Sanctuary (NMS) is a cooperative effort of the U.S. Geological Survey (USGS) and the National Oceanic and Atmospheric Administration, with technical support from the University of New Brunswick and the Canadian Hydrographic Service. The maps generated from this undertaking are based on a 1994–96 survey that used a multibeam echo sounder to map 1,100 square nautical miles of the sea floor (fig. 1). The technology and methods of image acquisition and topographic contouring that were used are described in publication 4 in the References section. USGS Scientific Investigations Maps (SIM) 2840–A to –F constitute a six-map (twelve-sheet) series in digital (DVD-ROM) format. The first three maps, SIM 2840–A, –B, and –C, were previously published on paper as USGS Geologic Investigations Series Maps I–2676–A, –B, and –C (publications 43–45 in the References). Preliminary versions of those three maps also had been released earlier on a CD-ROM as USGS Open-File Report 00–410 (publication 42).

The map area shown here is a composite of 18 individual quadrangle maps (fig. 1). Two map series of the 18 quadrangles have been published at a scale of 1:25,000 and show sea floor topography (publications 4–22) and sun-illuminated sea floor topography (fig. 2; see publications 23–41). Selected sea floor maps, photographs, CD-ROMs, fact sheets, posters, and geographic names related to research conducted in the Stellwagen Bank NMS region are available online at

USGS Web site <http://woodshole.er.usgs.gov/project-pages/stellwagen/index.html>. See the References section for a complete numbered list of publications.

On the maps presented in this series, the locations of the corners of the 18 quadrangles are shown for reference as ticks labeled outside the map edges, and (on maps C and E) as large crossticks within the map area. Maps A, B, D, and F show the boundaries of the individual quadrangles. On the maps that show sun-illuminated sea floor topography, blank spaces represent areas of no data.

Sea floor ruggedness

Terrain ruggedness index

Map D comprises five sheets showing various combinations of contoured and sun-illuminated topographic imagery and presentation of sea floor ruggedness. Our use of the terrain ruggedness index (TRI) concept is based on an approach developed by Riley and others in 1999 (publication 48) to calculate differences in elevation between neighboring areas of the Earth's surface. On this map the TRI uses information from the digital bathymetric (topographic) dataset to calculate the ruggedness of the sea floor.

On Sheets 1 to 5 we have simplified the TRI of Riley and others (publication 48) to represent the average change in elevation in meters between a center cell (image pixel) and its eight neighboring cells, arrayed in a three-pixel by three-pixel format (publication 46). Each pixel represents an area measuring 13 m on a side. Therefore, the TRI shows the average change in elevation between a central pixel measuring 13 x 13 m (169 m^2) and the surrounding eight pixels ($1,352\text{ m}^2$). No point in the nine-pixel area lies more than 18.4 m from the central pixel. The resolution of the bathymetric dataset determines the resolution of the seabed features that can be recognized by using this analytical technique. For example, terrain ruggedness indices derived from 13-m-pixel data are not comparable with TRI values of the same magnitude that have been derived from 10-m-pixel data.

Average changes in elevation (the terrain ruggedness, or TRI, values) are shown on this map in three intervals: >30 to 100 cm, >1 to 2 m, and >2 to 6 m. All map sheets except Sheet 1 show in gray tones those areas having a TRI $\leq 30\text{ cm}$. Sheets 1 and 2 show the entire range of sea floor ruggedness in the region, where ruggedness values range incrementally from >30 cm to 6 m and are shown in color (fig. 3). Sheets 3, 4, and 5 emphasize selected sea floor ruggedness intervals, in color. Sheet 3 shows only the ruggedness interval between >30 and 100 cm, in 10-cm increments; Sheet 4 shows only the ruggedness interval between >1 and 2 m, in 50-cm increments; and Sheet 5 shows only the ruggedness interval between >2 and 6 m, in 100-cm increments.

On these maps, we have taken a new approach in displaying sea floor ruggedness values by portraying them over a range of four elevation-change intervals, each in different increments, in order to recognize and illustrate better the variety of features of varying sizes that shape the seabed. We found that displaying ruggedness values only in 10-cm increments produced numerous TRI increments; and the many different colors required to represent them made it difficult to interpret seabed features. Conversely, by displaying ruggedness values only in increments of several meters, we could not clearly differentiate features such as small ridges and mounds whose lesser relief provides the structural setting for the geological and biological processes that form important seabed habitats.

Interpretation

The description of seabed features and bottom types in this discussion is based on topographic imagery and backscatter intensity (Maps B and C of this series), on video and (or) photographic imagery from 2,868 stations (Map F, Sheet 3 of this series), and on geological sediment texture analysis from 2,633 stations in the map region.

Gray tones on the map (Sheets 2–5) are areas having terrain ruggedness values in the 0- to 30-cm range that are characteristic of the following types of terrain: (1) smooth basin floors (Stellwagen and Scantum Basins); (2) smooth, gently-sloping bank margins (northern margin of Northwest Corner; southern Stellwagen Bank); (3) very low dunes, ridges, and mounds (northeastern Stellwagen Bank); (4) shallow irregular depressions (Western Spur, Lower Stellwagen Bank); and (5) shallow, elongate iceberg scours (Lower Jeffreys Ledge).

Ruggedness values in this interval also depict unnatural-looking stripes and patterns oriented parallel or perpendicular to survey tracklines that are artifacts of data collection (Stellwagen and Scantum Basins; Jeffreys Ledge and Stellwagen Bank). These artifacts, when represented by the TRI on the map, tend to obscure real seabed features, and it is preferable to rely on the sun-illuminated topographic imagery alone (not the TRI) for recognition of feature types that have ruggedness values in the 0- to 30-cm range.

Pink, purple, blue, turquoise, and dark-green tones on the map represent ruggedness values in the >30- to 100-cm range, in 10-cm increments (Sheets 1, 2, 3) and depict a wide range of small-scale features such as (1) boulder ridges derived from glacial eskers and moraines on bank upper surfaces (Gloucester Bank, Polygon Bank, Ellipse Bank, Tillies Bank, Jeffreys Ledge); (2) irregular basin floors (East and West Tillies Basins, base of Polygon Bank, base of East Ninety Bank); (3) deep, elongate iceberg scours (eastern side of the map region northward from 42°30' N.); (4) sand dunes (northeast Stellwagen Bank at 42°25' N., 70°12' W.; west of Ninety Meter Banks along 70°07.5' W.); and (5) gentle slopes of banks, valleys, and basins (Gloucester Bank, Thacher Bank, parts of Jeffreys Ledge and Stellwagen Bank).

Yellowish-green, yellow, orange, and red tones on the map represent ruggedness values in the >1- to 2-m range (in 50-cm increments) and in the >2- to 6-m range (in 100-cm increments) (Sheets 1, 2, 4, 5) and outline banks and basins carved from the sea floor by glacial ice. These ruggedness values occur on the following large-scale features: (1) steeply sloping flanks of large banks bounding large basins (Southwest Corner, Western Spur, Western Edge, Northwest Corner, Lower Stellwagen Bank, southern part of Jeffreys Ledge); (2) small banks separated by narrow, deep basins (Tillies Bank, Creed Ridge, Polygon Bank, Ellipse Bank, Ninety Meter Banks); (3) bank remnants that lie within large basins (East and West Breakwater Banks, Fifteen Bank, The Stone Wall, Scantum Spur); and (4) steep bedrock hills (East and West Pigeon Hills, Sanctuary Hill, East Hill).

On Sheets 1 to 5, the areas of the sea floor represented by the four TRI intervals (0–30 cm; >30–100 cm; >1–2 m; and >2–6 m) were calculated for each of the 18 quadrangles as well as for the area of the Stellwagen Bank NMS that lies in each quadrangle (see table 1). By far, the largest component of sea floor in the mapped area (85.4 percent) is relatively smooth (TRI 0–30 cm), and a comparison with the backscatter intensity map (Map C of this series) shows that seabed types with this TRI have sediment textures that range from mud to sand to gravelly sand. Seabed that is somewhat more rugged (TRI >30–100 cm) composes the next largest area of the region (12.8 percent) and represents a wide range of sediment textures that include mud, sand and gravel, and boulders; and features such as boulder ridges, mud-draped gravel mounds, iceberg scours, and low-angle slopes. Sea floor having the highest ruggedness values (TRI >1–2 m and >2–6 m) makes up only 1.8 percent of the seabed and typically is found on the relatively

steep slopes of bedrock outcrops and flanks of banks covered by mud, sand, and gravelly sand. These values for the region as a whole also are representative of the seabed within the Stellwagen Bank NMS that is outlined by the dashed line on the map.

Sea floor ruggedness is not distributed evenly throughout the map region, and this is reflected in the color intervals on the map and in the area calculations in table 1. The highest topographic variability, and the greatest range in ruggedness values, occur (1) where there are many small close-lying banks and basins (Tillies; Polygon; Ellipse Bank and Stenos Basin; Creed Ridge and Basin; Ninety Meter Banks); (2) in the vicinity of bedrock outcrops (Sanctuary Hill, East Hill, East and West Pigeon Hills), and (3) along the margins of large banks (Stellwagen Bank and Jeffreys Ledge). Upwelling and oceanographic temperature fronts characteristically occur in areas of high topographic variability.

Relatively smooth seabed having TRI values in the 0- to 30-cm range constitutes 89 to 98 percent of the sea floor in 10 of the 18 quadrangles (1–9, 16) and 81 to 85 percent of the sea floor in 4 other quadrangles (10, 12, 13, 17). In Quadrangle 10 of this latter group, 81.2 percent of the seabed has a TRI index of 0 to 30 cm and is relatively smooth; but 16.6 percent of the remaining seabed has an index of >30 to 100 cm, much of which represents boulder ridges (see Map F of this series). The remaining four quadrangles (11, 14, 15, 18) show the highest topographic variability, and each has less than 80 percent relatively smooth seabed (TRI 0–30 cm). In Quadrangle 11, 33.5 percent of the seabed has a TRI index of >30 to 100 cm, which represents to a large extent gently inclined bank and basin margins and to a small extent boulder ridges; 11.2 percent of the quadrangle has a TRI index of >1 to 6 m, which represents steeply inclined bank margins. Quadrangle 14 lies on the northern boundary of Quadrangle 11 and is somewhat similar to it geomorphologically; 20.7 percent of the seabed has a TRI index of >30 to 100 cm (owing primarily to gently inclined bank and basin margins and boulder ridges), and 6.4 percent has a TRI index of >1 to 6 m (steeply inclined bank margins). Quadrangles 15 and 18 contain large areas of seabed having a TRI index of >30 to 100 cm (21.7 and 39.9 percent, respectively) that represents iceberg scours that are 5 to 10 m deep, 50 to 100 m wide, and up to several kilometers in length.

The TRI alone does not allow reliable interpretation or comparison of sea floor compositions or feature shapes. Seabed terrains having similar ruggedness values can represent a diverse suite of bottom types. Terrain ruggedness analysis is useful for describing sea floor geomorphology and for identifying the effects of seabed processes when combined with interpretations of seabed sun-illuminated topographic imagery, backscatter intensity, video and photographic imagery, and sediment texture analysis. The map region is characterized by highly variable seabed topography. Terrain ruggedness indices are portrayed in 10-cm, 50-cm, and 100-cm increments in order to delineate relatively small but significant features (boulder ridges; irregular basin floors; deep, elongate iceberg scours; sand dunes; low-angle slopes of banks, valleys, and basins) from large features (steep flanks of large banks bounding large basins; small banks separated by narrow, deep basins; bank remnants that lie within large basins; and steep bedrock hills).

Seabed processes alter seabed ruggedness over time. Sediment deposition decreases ruggedness by smoothing small-scale features (for example, mud deposited on boulder ridges) and by reducing the steepness of large-scale bank margins (for example, sand eroded from the bank top and transported to the bank margin). Sediment erosion increases small-scale ruggedness by removing sand and mud from glacial features to leave sharply defined boulder and cobble ridges. See Map E of this series for a discussion of sea floor geomorphology based on seabed slope analysis.

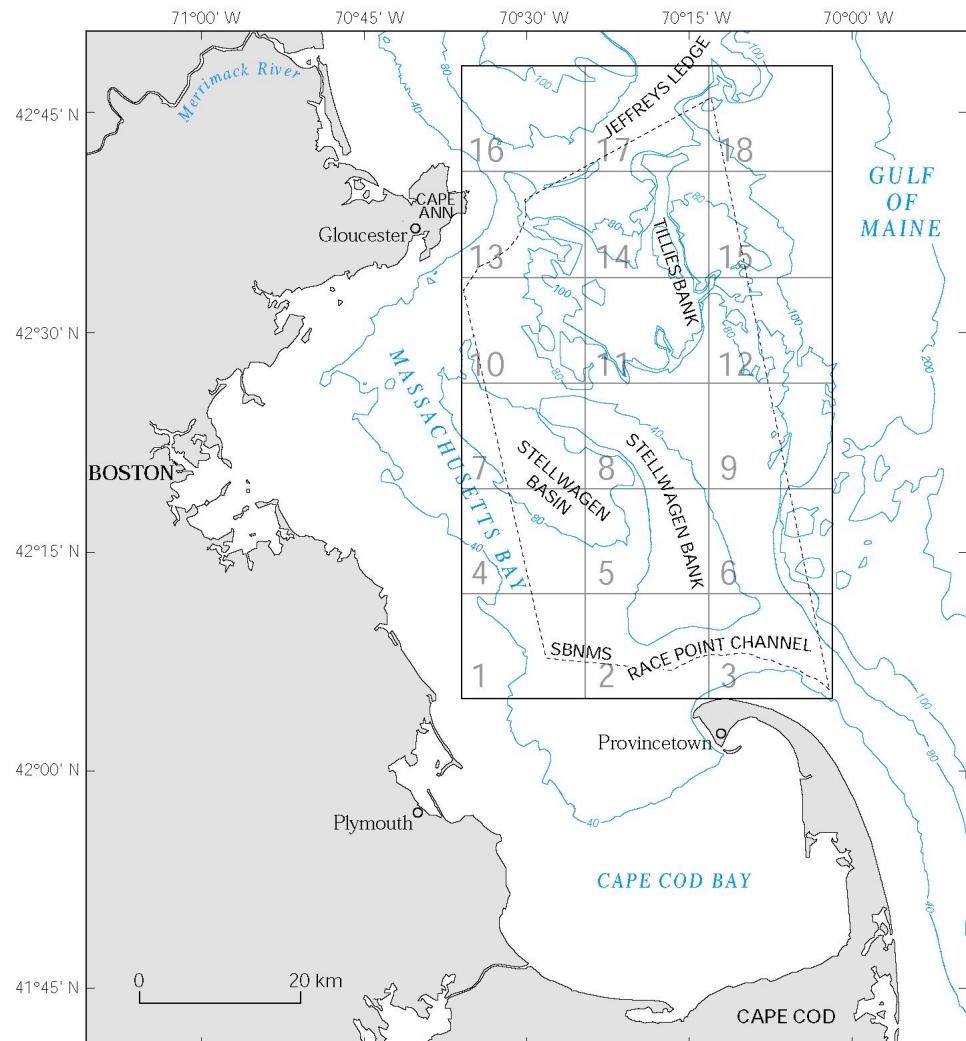

Figure 1. Regional setting of the map area (outlined in black). Publications specific to the entire map area or to individual quadrangles 1–18 (outlined in gray) are listed in the References section. Stellwagen Bank National Marine Sanctuary (SBNMS) boundary is shown as a dashed line. Bathymetric contours are labeled in meters.

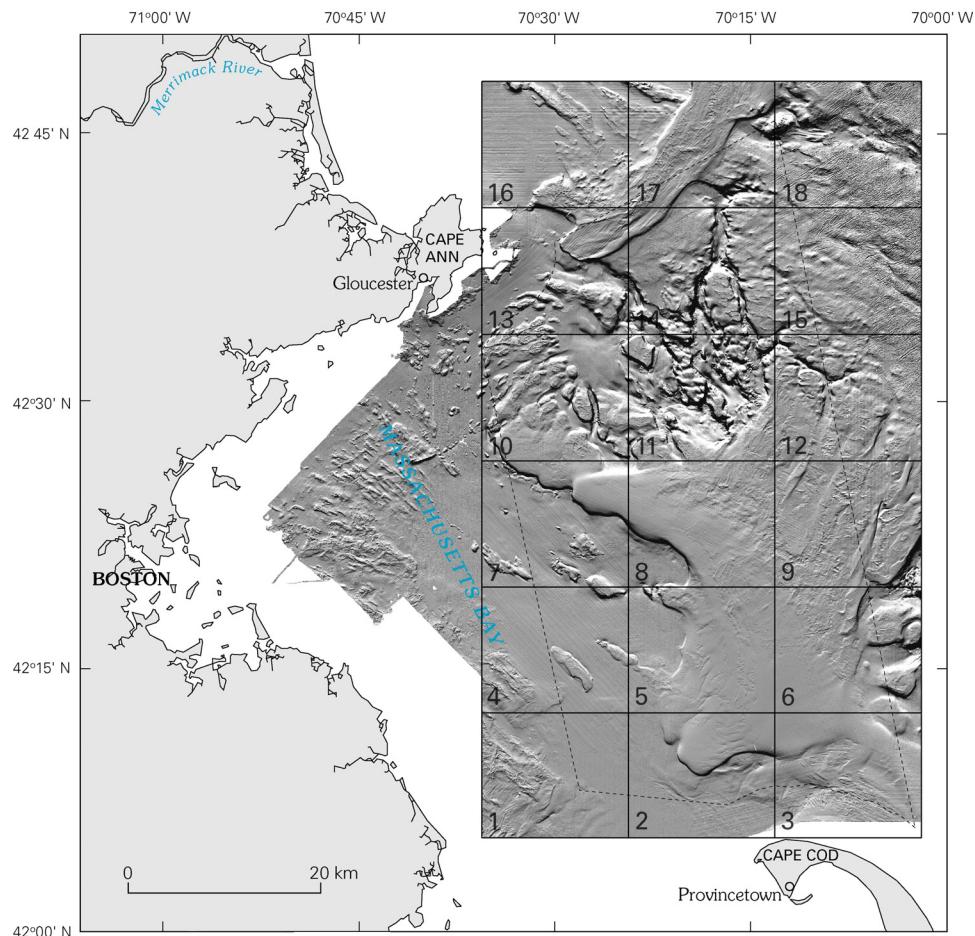

Figure 2. Sun-illuminated sea floor topographic imagery of the Stellwagen Bank National Marine Sanctuary and Massachusetts Bay region, and the 18 quadrangles of the map area. Dashed line is the sanctuary boundary.

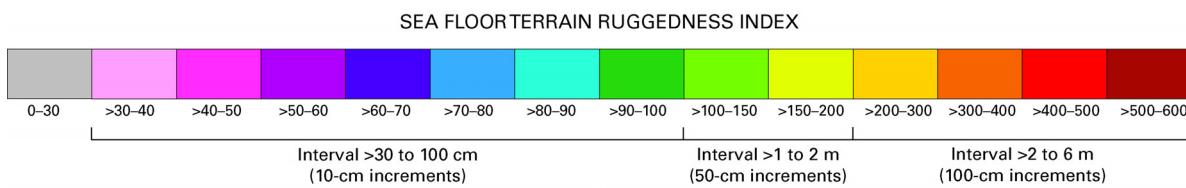

Figure 3. Sea floor terrain ruggedness index (TRI). Colors represent the average change in elevation, in centimeters, between a central area (a 13- x 13-m pixel) and the eight pixels that surround it (total area analyzed is three pixels by three pixels, or 39 x 39 m in size). For example, on the map blue represents central pixels having an average elevation change of >70 to 80 cm with respect to their surrounding eight-pixel areas. Note the elevation-change increments in the color scale vary from 10 cm to 50 cm to 100 cm. A filter was applied to the ruggedness index image to smooth the boundaries between the mapped intervals. The filter calculated the mean of the TRI value of each pixel and its eight neighboring pixels in a three-pixel by three-pixel grid that measures 39 x 39 m. Areas of ruggedness were calculated using this filtered image; see table 1.
